

ABSTRACT:

An internet receiving arrangement, which is connected to the internet and which may take the form of, for example, an internet radio (1), an internet television set (21) or an internet read apparatus (22), stores internet addresses (ASI) of information servers (3, 4, 5) which provide information data (AD, AVD, BD, ND, ZD) which are processable by the internet receiving arrangement. The internet receiving arrangement has quality test means (15) for testing whether received information data (AD, AVD, BD, ND, ZD) have a satisfactory quality. Only when the quality value of the received information data (AD, AVD, BD, ND, ZD) detected by the quality test means (15) is below a quality threshold value the internet addresses (ASI) stored in the internet receiving arrangement are updated with internet addresses (ASI) of the information servers (3, 4, 5) which are stored in an address server (6) connected to the internet (NET).
